Atmospheric Research

# The Need for Automated Turbulence Reports

---

- Turbulence can be a very dynamic and spatially localized phenomena – hence the need for real-time measurements.
- Pilot reports are problematic in that they are subjective measures of the aircraft response to the turbulence – not quantitative measures of the atmosphere.

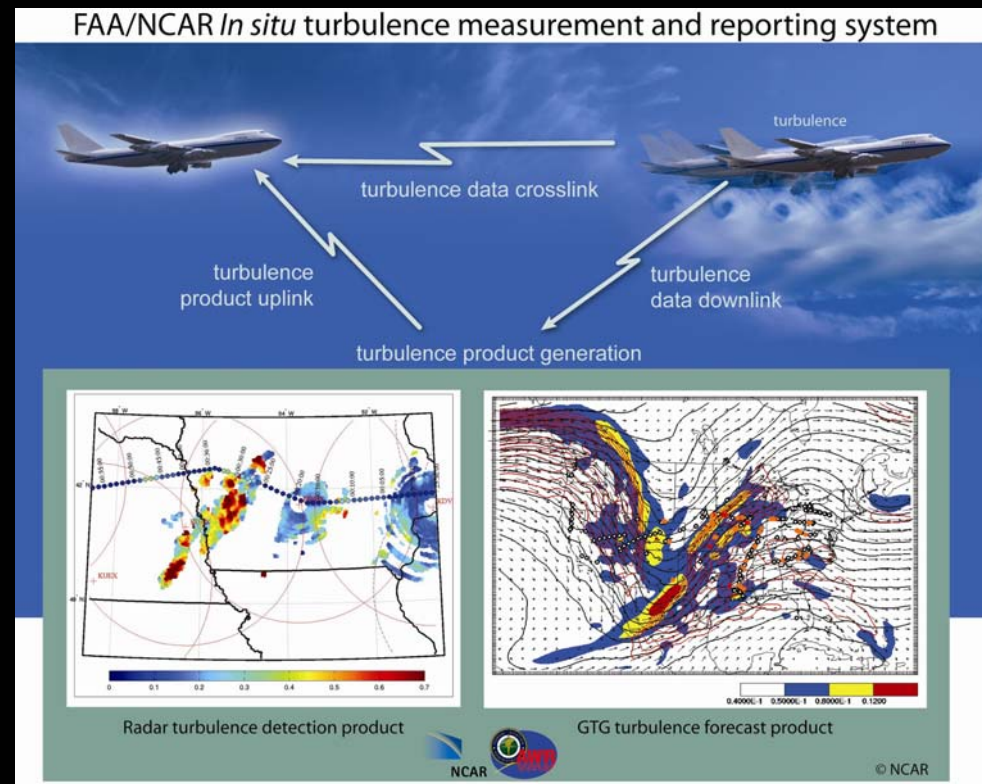

# *In situ* Turbulence Measurement and Reporting System

**Goal:** To augment/replace subjective PIREPs with objective and precise turbulence measurements.

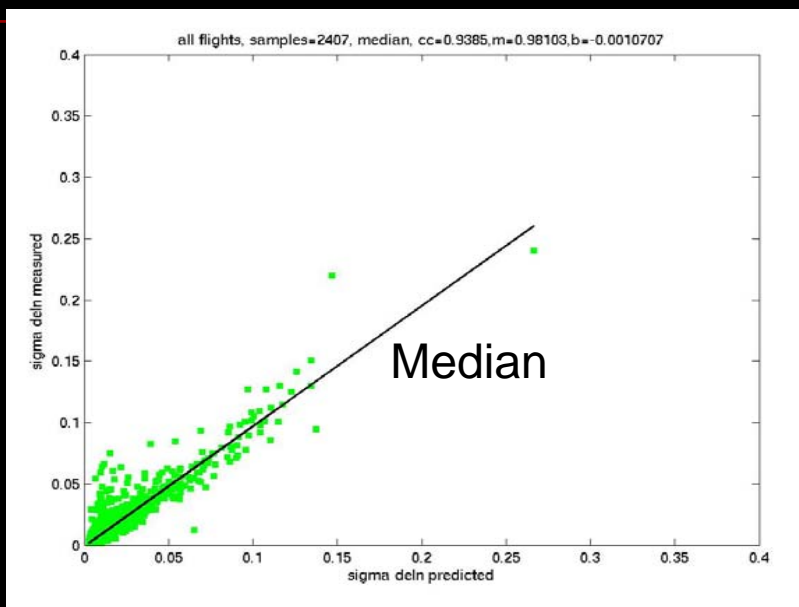

## **Features:**

- Atmospheric turbulence metric: eddy dissipation rate, (EDR).
- EDR can be scaled into aircraft turbulence response metric (RMS-g).
- **Adopted as ICAO Standard**

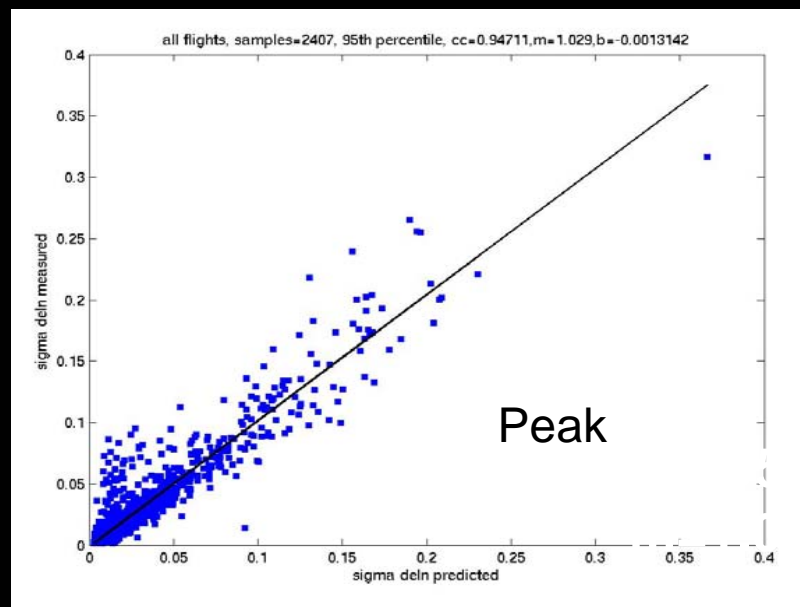

# Conversion Between EDR and RMS-g: Illustrated with Data from NASA B-757 Aircraft

Measured RMS-g

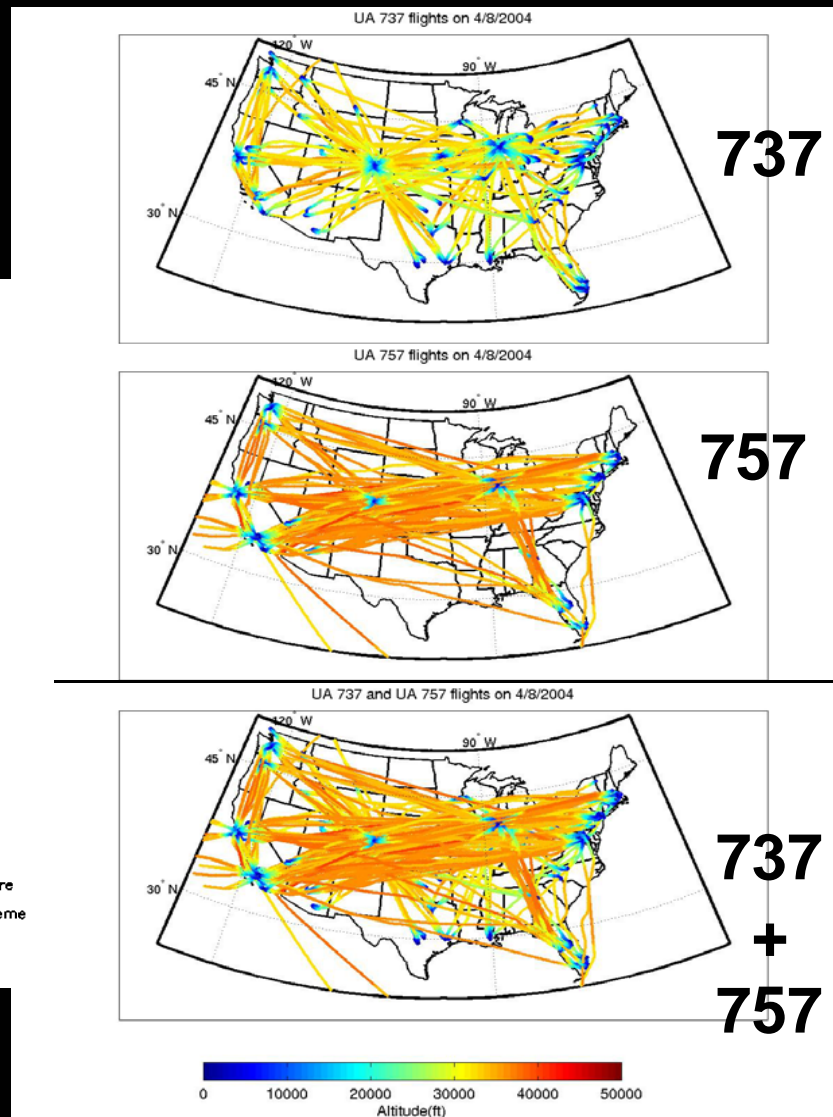

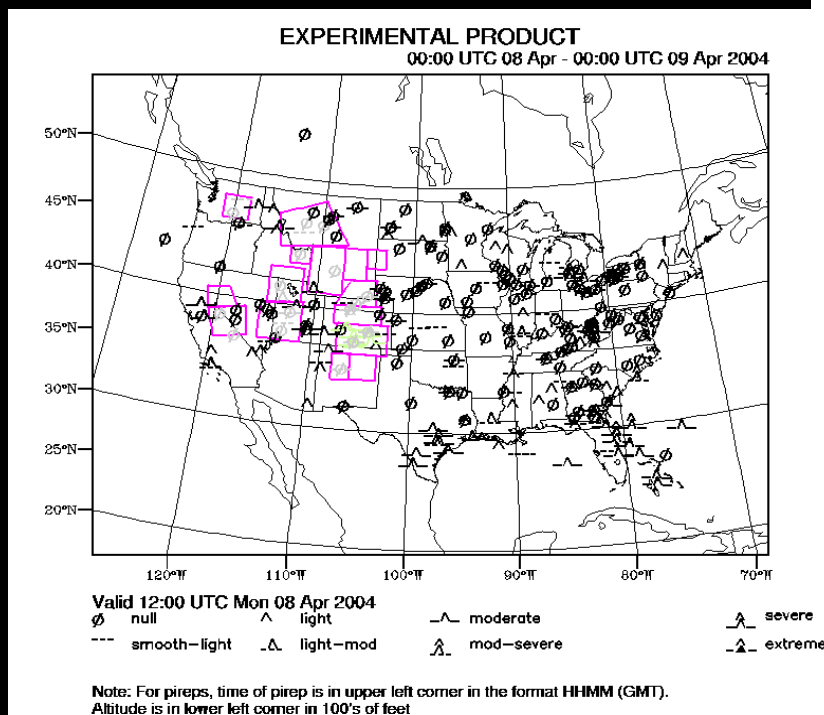

EDR-predicted RMS-g

2407 one-minute samples

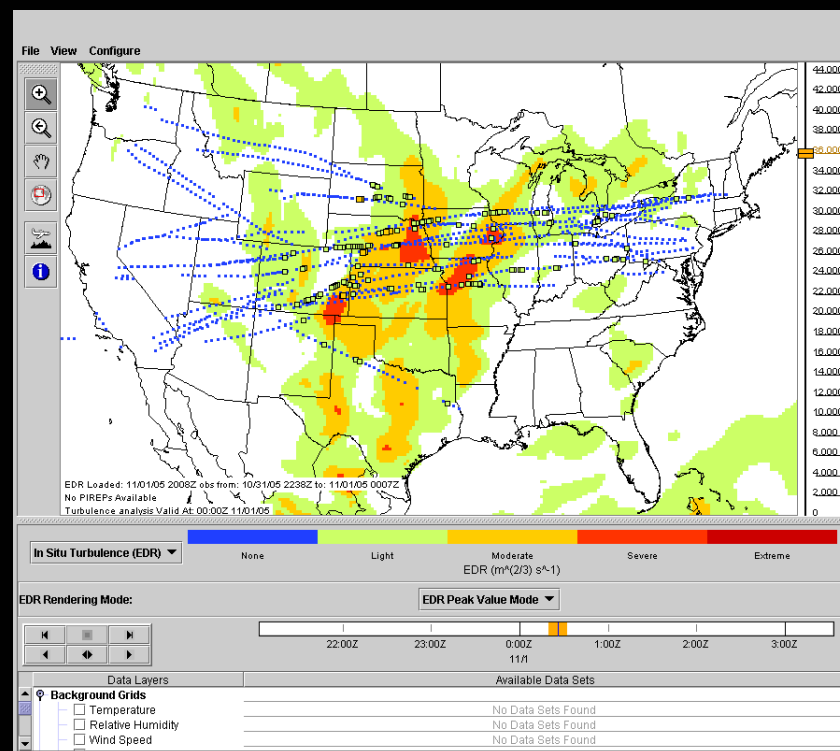

# Increase in Spatial/temporal Coverage: UAL EDR Reports Compared to pireps

1.3 million EDR reports/month from 100 or so aircraft - compared to 55k pireps from all aircraft. Imagine with 400 SWA aircraft added!

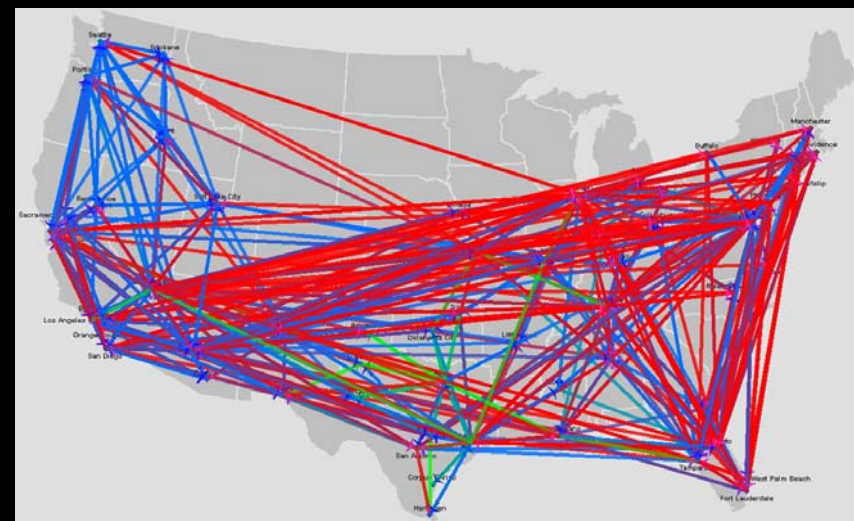

# EDR on Experimental ADDS

- Display contains EDR reports, pIREPs, GTG.
- Movie loops, cross-sections, etc...
- Currently in use by UAL Meteorology.
- Soon to be in use by UAL Dispatch and AWC forecasters.

# Major Upcoming Activities

- SWA implementation in CY06.
- Uplink demonstration with UAL in CY06.
- EDR ingest into GTG2: operational, Fall '06.

SWA Route Structure
